In a jet engine the turbine is designed to provide just enough output to drive the compressor and auxiliary devices. The stream of gas then leaves the turbine at an intermediate pressure (above local atmospheric pressure) and is fed through a nozzle to produce thrust. Mainshaft seals are used in gas turbine engines to restrict gas leakage into the bearing compartments (sumps). The air leaking through the seal prevents oil leakage out. In some engines the gas pressure and temperature are relatively low, so that a single labyrinth seal to restrict gas leakage into the sump is adequate (Fig. 1).
